

Project Ideas for the LandingAI Financial AI Hackathon

The goal is to build **intelligent financial agents** using LandingAI's Agentic Document Extraction (ADE) plus LLMs and agentic frameworks ¹. LandingAI's ADE can "capture complex layouts, including checkboxes and visual elements," and even extract data from charts, tables and images ² – making it ideal for parsing financial forms, contracts, reports and the like. Below are several complete project ideas that fit the financial track and leverage ADE+LLMs to solve real problems:

1. KYC/Onboarding Automation Agent

Financial institutions spend enormous effort manually reviewing customer documents (IDs, bank statements, credit reports, etc.) during onboarding. An **AI KYC Agent** could use ADE to extract data from unstructured KYC paperwork (passports, driver licenses, proofs of address, tax forms, etc.) ³ ⁴. For example, the system could automatically parse identity fields, financial info and risk data, then route those to an LLM or rule engine for verification and scoring. Key steps might include:

- **Document Parsing:** ADE processes diverse forms (PDFs, scans) to capture names, account numbers, incomes, etc. from KYC documents ³ ⁴.
- **Agent Orchestration:** An agent (e.g. LangChain or LangGraph) sequences tasks: it might invoke a credit-check API or use an LLM to interpret extracted data, flagging any anomalies (e.g. mismatched name/address) or generating a summary risk assessment.
- **Compliance Check:** The agent cross-references extracted data against watchlists or regulatory requirements (e.g. sanctions lists). AI for compliance "can streamline regulatory processes, detect risks, and reduce manual workload" ⁵, so automating KYC yields huge efficiency gains (reducing human error and cost).

Why it wins: Automated KYC/onboarding addresses a critical pain point in banking. As [10] notes, onboarding involves "reviewing KYC documents, identity proofs, and other paperwork" that "often arrives in unstructured formats" ³. By combining ADE with an LLM-based agent, this project could cut weeks of work into minutes.

2. Contract/Compliance Document Summarizer

Companies need to review lengthy financial contracts, reports and regulations for compliance. An **AI Compliance Agent** could use ADE to parse clauses from contracts or regulatory texts and an LLM to summarize or answer questions about them. For example:

- **Text Extraction:** ADE extracts text and structure from PDFs of contracts, prospectuses, loan agreements or regulatory filings (e.g. SEC releases). It can capture tables of terms, checkbox clauses, and embedded images. ²

- **Document Analysis Agent:** The agent feeds extracted content to an LLM. The LLM could be prompted to generate an executive summary (e.g. “List the key obligations and deadlines in this contract”) or highlight potential compliance issues. This mirrors how 88% of compliance use cases involve “summarizing documents” ⁶ .
- **Risk Alerting:** The agent can flag high-risk clauses (e.g. unusual fees, expiration dates) and even suggest contract redlines or compliance steps. In practice, AI for compliance often “automates rule checks and risk detection” and generates audit reports ⁷ , so this agent would bring those benefits to contract review.

Why it wins: Document summarization is a proven value-add: a survey found summarizing and reviewing documents are the **top two AI use cases in compliance** ⁶ . A tool that turns dense financial/legal documents into concise insights would save countless hours in due diligence or audit prep. It directly leverages ADE’s strength (complex document parsing) and the agility of LLMs to produce actionable summaries.

3. Earnings Report & Financial Analysis Agent

Analysts spend days poring over quarterly earnings reports and financial statements. An **AI Analytics Agent** could automate this: ADE would pull numeric data and text from filings, and an LLM agent would generate insights. For example:

- **Data Extraction:** Use ADE to capture financial tables and narrative from a company’s 10-K/10-Q or earnings PDF. It can read charts, footnotes and tables (e.g. revenue by segment, balance sheet items) with high accuracy ⁸ .
- **Analysis Workflow:** An agentic framework (e.g. LangGraph) orchestrates multiple analysis steps: computing growth rates, comparing actuals vs analysts’ consensus, or integrating live market data (e.g. stock price changes). AWS envisions an agent doing exactly this – processing earnings reports and “multiple complex steps: document processing, data extraction, numerical analysis...” ⁹ .
- **Insight Generation:** Finally, the agent asks an LLM to contextualize: e.g. “Company X’s Q3 revenue was up 10% vs last year, driven by product Y; however, margins declined due to higher costs.” These natural-language insights make financial data digestible.

Why it wins: This fits the hackathon’s call for “real-time” financial analysis. By automating report analysis, the project targets a core finance use case. AWS itself points out that agentic AI can transform how analysts work by autonomously generating such insights ⁹ . A polished demo (e.g. uploading an earnings PDF and instantly getting a Q&A report) would be impressive.

4. Invoice/Expense Fraud Detection Agent

Many organizations lose money to payment fraud in accounts payable. An **Accounts Payable AI Agent** could parse invoices and detect anomalies. Key components:

- **Invoice Digitization:** Use ADE to process large volumes of invoices, purchase orders, receipts and expense reports (often scanned documents). ADE can read handwritten notes, checkboxes (e.g. “paid” stamps), and line-item tables ⁸ .
- **Cross-Verification Agent:** The agent cross-checks extracted invoice data (vendor name, bank account, totals, invoice number) against trusted records (vendor master, past payments). As one

article notes, AI “can validate more complex information, like vendor names, bank accounts, tax IDs, and invoice totals, across multiple data sources” ¹⁰ . The agent flags inconsistencies (e.g. new vendor suddenly getting a large payment, duplicate invoice number) for review.

- **Anomaly Alerts:** In real time, the agent can alert finance staff if it sees suspicious patterns (unusual amounts, off-hour payments, etc.). Modern AI picks up on what rules-based systems miss ¹⁰ , preventing fraud before funds are disbursed.

Why it wins: Fraud detection in payables is a high-impact problem. Nearly **half of enterprise invoices are paper-based** ¹¹ , so automating their review is hugely valuable. An AI agent that “automates accounts payable fraud detection” directly addresses a real pain point and showcases ADE’s ability to handle messy invoice documents. The hackathon prizes “real-world feasibility,” and preventing fraud is a very tangible business use case.

5. ESG Data Extraction & Reporting Agent

Environmental, Social and Governance (ESG) compliance is booming in finance. An **AI ESG Agent** could automatically extract sustainability data from annual reports and generate ESG summaries. For example:

- **Report Parsing:** ADE processes sections of 10-Ks or sustainability reports (carbon emissions tables, social responsibility narratives, board diversity charts, etc.). It can pull metrics like CO₂ output, energy usage, or workforce diversity numbers from complex report layouts.
- **ESG Analysis Agent:** An agent asks an LLM to interpret the data: e.g. “Summarize Company Y’s ESG performance relative to sector benchmarks,” or “Prepare a summary of governance changes disclosed in this report.” This leverages the same document-to-insight workflow as above.
- **Compliance Mapping:** The agent could even map findings to standard frameworks (ISSB, GRI, etc.). For instance, as one AI tool advertises, a dedicated ESG agent “analyzes financial filings, sustainability reports, and governance documents to extract environmental metrics, social impact indicators, and governance data” ¹² . The output might be an automatically generated ESG report or scorecard.

Why it wins: ESG data is critical for investors and regulators, but very time-consuming to gather manually. An AI agent that builds an ESG profile from existing documents would be novel and valuable. It clearly stays in the financial track (investment compliance) and fully uses ADE’s multi-modal capabilities. Citing [22]: specialized AI already exists to “analyze financial filings and sustainability reports” for ESG metrics ¹² – this project could be a compelling demo of that idea.

Each of these ideas integrates **LandingAI’s ADE** (for document parsing) with LLMs/agents, and targets a concrete financial problem. They align with previous hackathon winners (e.g. due-diligence search, claims automation ¹³) but tackle new domains. By solving genuine industry pain points (KYC bottlenecks, compliance workloads, fraud loss, ESG reporting etc.), these projects would have the scope and impact to stand out and *potentially* win the championship.
